

Economics of Team-based Care in Controlling Blood Pressure

A Community Guide Systematic Review

Context: High blood pressure is an important risk factor for cardiovascular disease and stroke, the leading cause of death in the U.S., and a substantial national burden through lost productivity and medical care. A recent Community Guide systematic review found strong evidence of effectiveness of team-based care in improving blood pressure control. The objective of the present review is to determine from the economic literature whether team-based care for blood pressure control is cost beneficial or cost effective.

Evidence acquisition: Electronic databases of papers published January 1980–May 2012 were searched to find economic evaluations of team-based care interventions to improve blood pressure outcomes, yielding 31 studies for inclusion.

Evidence synthesis: In analyses conducted in 2012, intervention cost, healthcare cost averted, benefit-to-cost ratios, and cost effectiveness were abstracted from the studies. The quality of estimates for intervention and healthcare cost from each study were assessed using three elements: intervention focus on blood pressure control, incremental estimates in the intervention group relative to a control group, and inclusion of major cost-driving elements in estimates. Intervention cost per unit reduction in systolic blood pressure was converted to lifetime intervention cost per quality-adjusted life-year (QALY) saved using algorithms from published trials.

Conclusions: Team-based care to improve blood pressure control is cost effective based on evidence that 26 of 28 estimates of \$/QALY gained from ten studies were below a conservative threshold of \$50,000. This finding is salient to recent U.S. healthcare reforms and coordinated patient-centered care through formation of Accountable Care Organizations.

Context

High blood pressure (BP) presents a substantial economic burden in the U.S., fueled by increased medical expenditures, reduced work-site productivity from associated absences, and premature death. Recent U.S. studies estimate annual costs at \$47.5 billion in direct medical expenses and \$3.5 billion in lost productivity.¹ High BP is an important risk factor for cardiovascular disease (CVD) and stroke: the 2014 statistical update from the American Heart Association estimated that CVD and stroke cost \$193.4 billion in

medical care and about \$122 billion in lost productivity from premature death in 2010.²

The objective of this review is to determine whether team-based care (TBC) for BP control is cost beneficial or cost effective. Briefly, in TBC, a nurse, pharmacist, or other healthcare personnel work together with a provider and patient to manage the patient's care. The Community Preventive Services Task Force (Task Force) recently recommended TBC to improve BP control³ based on strong evidence of effectiveness found in a Community Guide systematic review.⁴ This paper provides estimates of intervention cost, healthcare cost averted, productivity gains, and health effects associated with TBC interventions to improve BP control. These estimates are crucial for understanding the economic merits of TBC.

Evidence Acquisition

General methods for Community Guide systematic economic reviews are available at www.thecommunityguide.org/about/economics.html. Methods specific to the present review are detailed below.

A systematic review team (the team) was constituted, including subject matter experts on CVD from various agencies, organizations, and academic institutions together with qualified systematic reviewers from The Community Guide branch at CDC. The team worked under the oversight of the Community Preventive Services Task Force.

Conceptual Approach

Team-based care to improve BP control is a health systems–level organizational intervention that incorporates a multidisciplinary team to improve the quality of hypertension patient care. The team comprises the patient, the patient's primary care provider, and other professionals who support and share the responsibilities of hypertension care including medication management, patient follow-up and adherence, and self-management. The complete definition is at www.thecommunityguide.org/cvd/RRteambasedcare.html. TBC is usually implemented in private or public healthcare settings and is likely to be financed by healthcare organizations or covered by insurers. Thus, evaluation studies may take a healthcare system perspective that only considers costs and benefits of TBC related to the healthcare delivery system. Because the healthcare system perspective and broader societal perspective are each useful ways to assess economic effects of TBC, both perspectives were considered in this review.

Appropriate study design and measurement are important in identifying the true economic effect of an intervention, an important element of which is the use of a control group. Therefore, studies that included a control group and those in which the control group received usual care or treatment were identified.

Intervention cost is the monetized value of labor and non-labor resources needed to implement and maintain TBC to improve BP control; it reflects the incremental cost of TBC beyond the cost of usual care. The components of intervention cost are the cost of provider time, patient time, and rent and utilities.

The impact of TBC on healthcare cost is the difference in cost of healthcare products and services used by the intervention group and control group or the pre- to post-change where there is no

control group. The components of healthcare cost are outpatient visits, medications, hospital inpatient stays, emergency room visits, and patient time.

Effective TBC interventions to control BP lead to reduced systolic and diastolic blood pressure (SBP and DBP, respectively) and increase the number of patients achieving BP control. The reduction in BP, in turn, reduces morbidity and mortality and increases the quantity and quality of years lived, measured as quality-adjusted life-years (QALYs).

The expected economic benefit of TBC is the sum of savings from averted healthcare cost and the increased productivity of patients at their worksites owing to reduced morbidity and mortality. Cost-benefit analysis compares economic benefit to intervention cost, where both benefit and cost are monetized and expressed in dollar terms; an intervention is cost beneficial when economic benefit exceeds intervention cost.

The ratio of intervention cost to QALY gained produces cost utility, a type of cost-effectiveness assessment: an intervention is cost effective when cost per QALY gained is less than a conservative threshold of \$50,000.⁵ Because the threshold is based on net cost (intervention cost plus healthcare cost) per QALY gained, an additional set of estimates of net cost per QALY gained is also computed. This review defines other cost-effectiveness measures based on additional health outcomes: intervention cost per unit reduction in BP (\$/mmHg) and intervention cost per additional person achieving BP control. Interventions targeting BP control can be readily compared to each other based on results expressed as cost per unit reduction in BP or additional person achieving BP control. Results expressed as cost per QALY gained facilitate comparison of interventions to control BP with other health interventions.

For studies that reported an intermediate health outcome, such as reduction in SBP, along with the cost of intervention, reductions in SBP were converted to QALY gained using existing algorithms to allow estimation of cost per QALY gained. A comprehensive registry of cost-effectiveness studies on a wide variety of diseases and treatments was searched to identify studies that translated SBP to QALY (research.tufts-nemc.org/cear4/).⁶ Two search terms were used—*BP/hypertension* and *QALY*—so that the yield would be broadly inclusive. Review of titles and abstracts from 44 papers and further review of full text of 15 studies identified two studies^{7,8} that converted a reduction in SBP to QALY gained. Both studies were for populations with diabetes. The present review adopted the two conversion algorithms used in the studies.

This first reference study⁷ assumed that a 5.7-mmHg reduction in SBP sustained over a lifetime would result in a gain of 0.53 QALYs, where $QALY/mmHg=0.093$. The translation in this study conducted in the United Kingdom (UK) was based primarily on results from the UK Prospective Diabetes Study (UKPDS; www.dtu.ox.ac.uk/ukpds/), which followed a group of adults (mean age, 56 years) with diabetes over a period of 8 years. Risk of myocardial infarction and stroke were incorporated based on both the UKPDS⁹ and Framingham Heart Study^{10–12} with weights for QALY drawn from the CDC Diabetes Cost-Effectiveness Study Group.¹³ The second reference study⁸ demonstrated that each unit reduction in millimeters of mercury of SBP is associated with approximately 0.009 QALYs gained during each annual cycle of a simulation model. This study modeled the experience of a cohort of people with diabetes aged 20–74 years (mean age, 52 years) over 20 years. Risks of myocardial infarction, stroke, peripheral artery

disease, end-stage renal disease, and severe visual loss were drawn from the UKPDS¹⁴⁻¹⁶ and Framingham Heart Study,¹⁰ with QALYs based on patient-reported quality of life.¹⁷ The QALY gained per unit reduction in SBP in the two studies is not far apart, considering that the second study was focused on a slightly younger cohort and based on patient-reported quality of life.

Cost and economic benefit estimates from included studies were standardized to a per person per year basis when possible. All monetary values were then converted to 2010 U.S. dollars; the Consumer Price Index from the Bureau of Labor Statistics (www.bls.gov/cpi/tables.htm) was used to adjust for inflation and Purchasing Power Parity indices from the World Bank (data.worldbank.org/indicator/PA.NUS.PRVT.PP) to convert from foreign currencies. Considerable variability may remain, owing to various factors including composition of the team providing the care, allocation of activities among team members, and incomplete accounting for costs and benefits associated with the intervention. The major elements that drive intervention costs and benefits were identified a priori based on knowledge and information gained from peer-reviewed literature and subject matter experts. Finally, what variability remained was acknowledged by presenting medians of individual estimates with interquartile intervals (IQIs).

Team-based care interventions that go beyond BP control, with additional objectives such as treatment of hyperlipidemia and hyperglycemia, are likely to cost more to implement than interventions focused on BP control and also likely to avert greater healthcare cost when they are effective. Separate estimates are provided in this paper from the full set of studies and from the studies of TBC interventions that focused on BP control.

Search Strategy and Search Yield

Included studies came from two separate searches. First, a broad search for economic studies of interventions that focused on BP control was conducted by CDC's Division for Heart Disease and Stroke Prevention (DHDSP) from January 1985 to March 2012. Searched databases were OVID/Medline, EMBASE, PsycINFO, CINAHL, Sociological Abstracts, Web of Science, Cochrane, and EconLit. The search strategy used by DHDSP is available at www.thecommunityguide.org/cvd/supportingmaterials/SS-team-based-care-econ.html. Authors screened 9,152 titles from the DHDSP search for TBC intervention studies with economic outcomes, based on the conceptual approach for this review. In addition, any studies with economic information identified in the search for the review of TBC effectiveness⁴ were also included. That search strategy is available at www.thecommunityguide.org/cvd/supportingmaterials/SS-team-based-care.html. Screening from these two sources resulted in 31 included studies (Figure 1), where studies were included in the present review if they

1. met the intervention definition;
2. were in English;
3. were implemented in a high-income economy¹⁸;
4. reported the economic cost or economic benefit of the intervention;
5. had BP control as the primary intervention focus; and
6. did not include populations with secondary hypertension.

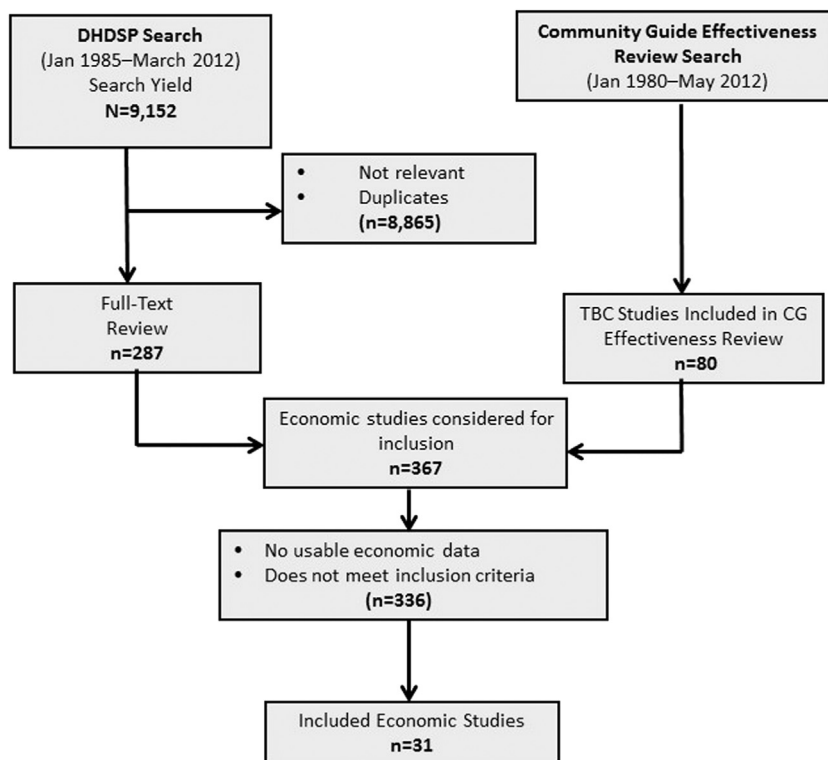

Figure 1. Flow diagram: number of studies identified, reviewed in full text, reasons for exclusion, and total number of included studies. CG, Community Guide; DHDSP, Division for Heart Disease and Stroke Prevention, CDC; TBC, team-based care.

Evidence Synthesis

Table 1 provides an overview of four characteristics of included studies: location, setting, presence of control group, and period of publication. Details of the included studies are available at www.thecommunityguide.org/cvd/supportingmaterials/SETecon-Team-Based-Care.pdf. Table 2 summarizes the type of economic analyses conducted in included studies.

Intervention Cost

This review identified three components of cost to implement TBC interventions: provider time, patient time, and rent and utilities. Studies that reported including two or more components provided “reasonably complete” accounting of intervention cost.

Table 3 shows the components included in the estimates of intervention cost reported in 20 included studies^{7,19–37}; two studies^{28,35} measured it as the post-cost minus pre-cost

for the intervention group; the remaining studies measuring it as the incremental cost over usual care. Confidence in the estimates was enhanced because most studies included important components of intervention cost and appropriately measured incremental cost. Further, the present review calculated medians and IQIs to draw attention to the central tendency rather than to the range.

Table 4 summarizes estimates for intervention cost per person per year from the included studies. Based on 29 observations from 20 studies, the median intervention cost of TBC was \$284 per person per year (IQI=\$153, \$670). The median intervention cost was \$359 for studies^{7,19,22–24,26,27,29,30,32,36} that were reasonably complete in their accounting of intervention cost, \$198 per person per year for studies^{19–24,29,30,33,35,36} that focused solely on BP, and \$225 for studies^{19,22–24,29,30,36} with both features. The cost of intervention was smaller where the focus was on BP control compared with interventions with one or more additional objective(s).

Impact on Healthcare Cost

Five components of healthcare cost were identified for analysis of the impact of TBC: outpatient visits, hospital inpatient stays, emergency room visits, medications, and patient time. The accounting of healthcare cost was considered reasonably complete when studies included three or more of these components. Table 5 shows the 20 studies^{19,24,26,29–31,34–47} that reported the components included in estimates for cost of healthcare, with more than half of the studies including at least three

components. Five studies^{26,31,40,42,44} measured the change as post-intervention healthcare cost minus pre-cost for the intervention group; the remaining studies

measured it as the incremental healthcare cost experienced by the intervention group over that experienced by the control group.

Table 6 summarizes estimates of healthcare cost impacts associated with the TBC intervention. One study⁴⁸ reported cost per person per year to be \$4,316 higher for the intervention group compared with usual care. This was considered an outlier and not included in Table 6 because the TBC involved post-acute home-based care of high-risk patients. Across 23 observations of healthcare cost impacts from 20 studies, the median was \$65 per person per year (IQI=−\$235, \$318). Ten of the estimates from ten studies^{19,26,37,38,40,42-45,47} were negative, indicating healthcare cost savings. With the focus on 11 studies^{19,24,26,29,30,35,37,38,40,43,44} that provided reasonably complete accounting, the median was a healthcare cost savings of \$77 per person per year (IQI=−\$436, \$98). Seven^{19,26,37,38,40,43,44} of these studies reported estimated healthcare cost savings from TBC.

Overall, evidence for TBC reducing healthcare cost was mixed, though most (64%) studies^{19,26,37,38,40,43,44} with a reasonably complete accounting of healthcare cost components indicated that TBC resulted in healthcare cost savings (Table 6).

For seven studies^{19,29,30,34-37} that reported both intervention cost and healthcare cost, the sum of the costs was computed as an estimate of the total cost of TBC, producing a median cost per person per year of \$329 (IQI=\$190, \$658).

Cost per Unit Reduction of Blood Pressure and Cost per Additional Person With Controlled Blood Pressure

Ten studies^{20,22,23,25,27,31,32,35-37} with 14 pairs of observations of intervention cost and reduction in SBP showed a median cost per unit of mmHg reduction in SBP of \$87 (IQI=\$52, \$202; Table 7). The median cost effectiveness of TBC in reducing DBP was \$102 per unit (IQI=\$51, \$123) based on 11 observations from nine studies.^{20,22,25,29-32,35,37} The health benefit from reduced BP is very likely positive for SBP/DBP ≤140/90 as recommended by the Seventh Joint National Committee (JNC-7) (www.nhlbi.nih.gov/health-pro/guidelines/current/hypertension-jnc-7), and previous studies have shown that the benefit becomes minimal for SBP and DBP below certain thresholds.⁴⁹ A positive intervention cost and no possibility of health benefit from reducing BP below these thresholds warrants further comment. Of ten studies, the mean SBP after the effect of intervention was >140 in three studies,^{20,25,31} 115-140 in seven studies,^{22,23,27,32,35-37} and <115 in no studies. Of nine studies, the mean DBP after the effect of intervention

was >90 for two studies,^{29,30} 70–90 in six studies,^{20,25,31,32,35,37} and at 68.8 in one study.²² Based on these means, it is likely that the reductions achieved in SBP/DBP from the interventions in this review fell within the beneficial range.

Several studies reported the incremental percentage of people in the TBC intervention group who achieved controlled BP. This measure of impact is important from a public health and healthcare organization perspective because it provides a reading on population status with

respect to uncontrolled BP. (Table 8 shows cost effectiveness derived from this outcome.) The median incremental cost per additional person achieving BP control was \$3,316 (IQR=\$2047, \$5422), based on 16 observations from 11 studies.^{7,21-26,30,32,36,37} The thresholds for BP control were DBP <90 in two studies^{21,30} from the 1980s, SBP/DBP <140/80 in one⁷ based on a diabetic population, and SBP/DBP <140/90 in the others. The cost per additional person achieving BP control may appear large relative to the median intervention cost or the cost per unit of BP reduction. However, two factors should be considered. First, it is the cost per additional person achieving BP control compared with usual care. Second, the intervention is not 100% effective and only part of the intervention group will achieve BP control. For example, even a large reduction in SBP starting from a high baseline may not indicate controlled BP.

Cost-Benefit Studies and Cost-Utility Studies

Cost benefit or cost per QALY outcomes are needed to draw conclusions on the economic value of an

intervention. Few included studies reported these outcomes: two studies^{19,26} reported benefit-to-cost ratios, two^{24,36} provided cost per life-year saved, and one⁷ estimated cost per QALY gained.

Cost-benefit studies. Two studies reported the ratio of the monetized value of intervention benefit to intervention cost as 12.1:1²⁶ and 10:1,¹⁹ respectively, indicating that TBC was cost saving, but several caveats apply. The first study²⁶ had multiple objectives beyond BP control, and healthcare cost estimates were for patients selected from a pool of high utilizers. The second study¹⁹ underestimated the cost of software development and deployment by simply dividing the fixed cost from the trial by the much larger number of people with high BP in the Quebec region, without considering issues of scalability.

Cost-effectiveness studies. One study⁷ reported a cost per QALY of \$4,763, which is far below the \$50,000 threshold for cost effectiveness. The estimate was based partly on measurements of intervention cost and SBP

^aThresholds for BP control: two^{21,30} studies from the 1980s were based on DBP <90, one⁷ based on SBP/DBP <140/80 for a diabetic population, and the remaining were based on SBP/DBP <140/90.

^bComponents of intervention cost were provider time, patient time, and rent and utilities. BP, blood pressure; IQR, interquartile interval.

reduction from an actual intervention; modeling of QALYs saved was based on the relationship between observed reduction in SBP and QALYs saved from a large population-based RCT.

Two other cost-effectiveness studies reported cost per life-year saved, one²⁴ ranging from \$48,995 to \$100,744 and the other³⁶ from \$23,299 to \$64,832. Finally, another study³¹ reported the cost of TBC in terms of observed averted health events, namely, \$64,610 per cardiovascular event averted and \$118,873 per chronic heart disease event averted. There is no standard threshold against which to compare these estimates of cost per averted health events to reach a determination about their economic value.

Cost-effectiveness studies (cost per quality-adjusted life-year): systolic blood pressure to quality-adjusted life-year converted studies. Ten included studies provided estimates for reductions in SBP but did not evaluate the long-term effects on morbidity and mortality. The team translated these results into two sets of cost-effectiveness estimates based on formulae

relating SBP reduction to QALY gained in two reference studies.^{7,8}

Fourteen observations of SBP reductions from the ten included studies^{20,22,23,25,27,31,32,35–37} were converted to QALYs (Table 9), with associated intervention costs discounted at 3% and summed over a 20-year expected lifetime. Applying the method from one of the reference studies⁷ to these data resulted in an estimated median cost per QALY gained of \$13,992 (IQR=\$8339, \$32292). Two observations from one study²³ produced estimates that were above the conservative cost-effectiveness threshold of \$50,000 per QALY, with one slightly more than \$50,000 and one slightly less than \$60,000. Applying the formula from the second reference study⁸ to the same data resulted in a median estimated cost per QALY gained of \$9,716 (IQR=\$5791, \$22425). Based on this formula, all 14 observations produced estimates that were below the threshold. Keeping in mind that the \$50,000 threshold is based on intervention cost plus the change in healthcare cost, an additional set of estimates for net cost per QALY gained was derived for three studies^{35–37} that reported intervention cost, healthcare

Table 9. Cost per QALY Gained Based on Conversion of Reduced SBP Attributable to Intervention

	Conversion method 1 ⁷	Conversion method 2 ⁸
No. of studies reporting intervention cost and SBP reduction	10 studies ^{20,22,23,25,27,31,32,35–37}	
20-year intervention cost per person (\$), median (IQR)	9,299 (4838, 11110)	
Reduction in SBP (mmHg), median (IQR)	6.70 (3.90, 7.43)	
20-year QALY gained, median (IQR)	0.623 (0.363, 0.691)	0.897 (0.522, 0.995)
20-year cost per QALY gained (\$), median (IQR)	13,992 (8339, 32292)	9,716 (5791, 22425)
Type of team member added		
Nurse ^{20,22,23,27,32,36}	24,042 (8836, 44752)	16,696 (6136, 31077)
Pharmacist and other ^{25,31,32,35,37}	10,244 (1934, 13992)	7114 (1343, 9716)
Baseline SBP		
> 140 ^{20,25,31,35}	5587 (1334, 9693)	3880 (927, 6731)
≤ 140 ^{22,23,27,32,36,37}	20,564 (11381, 41826)	14,280 (7903, 29045)

IQR, interquartile interval; QALY, quality-adjusted life-years; SBP, systolic blood pressure.

cost, and reduction in SBP. Estimates of net cost per QALY gained were \$3,641,³⁵ \$37,071,³⁶ and \$5,491³⁷ based on the method of the first reference study⁷ and \$2,529,³⁵ \$25,744,³⁶ and \$3,813³⁷ based on the second reference study.⁸

Several characteristics of the interventions were explored as explanatory variables for the variation observed in cost per QALY gained: implementation in a health system or community setting, type of team member added to usual care, management of medication, compared with usual care or not, and whether the baseline SBP was high or low relative to the 140 threshold. All studies included medication management or medication counseling. All studies had a control group that received usual care and all but two^{20,37} were implemented in healthcare settings. The results of the categorical analyses based on the remaining variables are presented in Table 9. It may appear that teams that added pharmacists and others had lower cost per QALY gained than those that added nurses. However, this difference in cost effectiveness may also be explained by different baseline rates for SBP because the same studies that used pharmacists and others had higher baseline SBP.

Conclusions

Summary of findings. Evidence of cost per QALY gained from this economic review indicates that TBC is cost effective in improving BP control.

Discussion

The major caveat in this review is that the formulae for the relationship between SBP and QALY were drawn from the experience of people with diabetes and comorbid high BP. It is not clear whether, and to what extent, limiting the study populations to people with diabetes leads to an overestimation or underestimation of the relationship between SBP and QALYs. Even though it is possible that the overall QALYs may be worse for diabetic patients than hypertensive patients, the relative impact of SBP reduction on the overall QALYs of diabetic patients compared with that of hypertensive patients is uncertain.

The cost of intervention and the impact on healthcare cost are key estimates reported in the included studies from which the present review drew findings about cost effectiveness and the cost impact of TBC on utilization of healthcare resources. The studies varied in completeness of accounting for components of these costs and in whether the increment in cost was measured relative to a control group. Despite these variations, the finding of cost effectiveness is credible given that most studies were reasonably complete in accounting for components of

intervention cost and all but two of the 28 cost per QALY estimates were below the conservative \$50,000 threshold. Net cost per QALY saved could be calculated only for three studies, but all three estimates were below the conservative threshold of \$50,000.

The generalizability of the review's results to practice is not seamless because a substantial proportion of the evidence is drawn from studies implemented in research settings. Also, the review's overall cost-effectiveness conclusion is based on modeled long-term outcomes. The incentives and protocols that bound provider and patient together as a collaborative team in research must be replicated or replaced with alternatives to implement the intervention in practice. Hence, multiple reimbursement systems (e.g., for pharmacy and medical benefits) will have to be coordinated and new services and providers may also have to be added to reimbursement systems. The change necessary in the organization, delivery, and reimbursement for care is feasible and sustainable, as demonstrated by the success of the Kaiser Permanente Northern California hypertension program.⁵⁰

By extrapolating reductions in BP found in trials to 20-year horizons of QALYs gained, the present review implicitly assumed that the TBC intervention is sustained and paid for over the same period. Over this long term, members of the team must receive compensation to ensure their continued participation. From a financial standpoint, the insurers/payers must find it in their interest to make a long-term commitment to support these teams and to pay individual providers, some of whom they had not dealt with directly. Arrangements by health plans to reimburse teams were far from prevalent during the periods covered in the included studies. By contrast, recent healthcare reform in the U.S. and the Affordable Care Act may promote TBC through Accountable Care Organizations by encouraging the formation of patient-centered teams and improving care coordination among clinicians.^{51,52}

Finally, it may be argued that individuals do not stay in health plans long enough for the plans to reap the financial benefits of some types of prevention,⁵³ but members with high BP are well served by TBC to bring their BP under control and manage any relapse.

Evidence Gaps

More complete and comprehensive reporting of cost and its components is needed. Some evaluation studies simply reported an aggregate estimate for intervention cost or healthcare cost without discussing the components. Many evaluations reported the aggregate estimate and listed the components but did not provide values for the components, precluding an analysis of which

components contributed the most to the aggregate estimate. An analysis of the components of cost or benefit reported in a body of evaluation studies would provide the data to determine what should be considered drivers of the estimated values.

More research is needed to see how variations in the TBC model (i.e., that employ different methods of patient engagement through differences in team structure and team activities) affect intervention cost and cost effectiveness.

Associated costs of the intervention were not always reported. A number of studies reported only healthcare cost impact, probably with the objective of determining if TBC is healthcare cost saving. However, a determination about economic value could not be drawn from these studies because the associated costs of intervention were not reported.

No evaluation study considered the impact of TBC on improved productivity at work. This review noted the omission of productivity considerations from intervention evaluations despite the fact that the magnitude of productivity losses attributable to CVD and stroke by themselves is highlighted in the burden literature.

Finally, a major gap in the economic evaluation literature for BP control is lack of a widely accepted standard relating reduced BP to QALY for the general population of people with high BP.

This review would not have been possible without the subject matter expertise and contributions of our coordination team in the Community Guide Branch at CDC, from other areas of CDC, and our external partners: David B. Callahan, MD, Office of Public Health Preparedness and Response, CDC; Diane Dunet, MPA, PhD, Division of Heart Disease and Stroke Prevention, CDC; external partners, Kimberly J. Rask, MD, PhD, Emory University, Atlanta; Daniel T. Lackland, DrPH, Medical University of South Carolina, Charleston; Barry Carter, PharmD, University of Iowa, Iowa City. The authors also acknowledge Randy W. Elder, PhD, Kate W. Harris, BA, Kristen D. Folsom, MPH, and Onnalee Gomez, MS, from the Community Guide Branch at CDC for their assistance throughout the review process.

With great sadness, the authors note the untimely passing of David B. Callahan earlier this year. We greatly valued his insight and contribution to the effectiveness and economic reviews.

The findings and conclusions in this report are those of the author(s) and do not necessarily represent the official position of CDC.

The work of Krista Proia, Gibril Njie, and Ramona Finnie was supported with funds from the Oak Ridge Institute for Scientific Education.

No financial disclosures were reported by the authors of this paper.
